Design Diary Entry Six

Airbnb

The Airbnb Application is to facilitate the discovery, booking, and management of accommodations for travelers around the world. Its primary usefulness lies in providing a platform where users can find a diverse range of lodging options, including vacation rentals, apartments, houses, and unique stays.

The target audience for the Airbnb app is diverse and specific, focusing on individuals with varying travel preferences and needs. It primarily includes travel enthusiasts who enjoy exploring new places and appreciate a range of accommodation options beyond traditional hotels. Budget-conscious travelers seeking cost-effective lodging alternatives, including vacation rentals or shared spaces, find value in the app. Airbnb also provides unique and unconventional stays such as treehouses, houseboats, or boutique accommodations. Individuals attending events or festivals in specific locations also benefit from the app by finding convenient and personalized lodging options. Lastly, local hosts interested in renting out their properties to travelers, thereby creating an additional income stream, contribute to the diverse ecosystem of Airbnb users.

I relied heavily on Airbnb for diverse vacation rentals in India, exploring unique accommodations from cozy apartments to homestays. It serves as a versatile platform for both international and domestic travel, seamlessly accessible on my iPhone and through web browsers. Recently, I used Airbnb to book accommodation for a conference in San Francisco, appreciating its reliability in providing a range of options. This consistent use underscores Airbnb's versatility and dependability in meeting my varied accommodation needs across different regions and purposes.

In this design diary entry, I'd like to share my recent experience with the Airbnb application, focusing on various cognitive design elements like affordance, signifiers, constraints, mapping, feedback, and discoverability. Airbnb is a platform that allows users to discover, book, and manage accommodations around the world, and my interactions with the app have been quite enlightening.

Affordance:

Airbnb excels in affordance by making it clear how users can navigate through the app. One prominent example is the "**Search bar**", which is typically located at the top of the screen. It's visually distinct and encourages users to search for accommodations, as it's one of the primary actions users take. Additionally, the bottom navigation and buttons for filters, and Wishlist provides clear affordances for users to filter results, save properties, and manage their reservations.

Signifiers:

Signifiers in the Airbnb app help users understand how to interact with different elements. For instance, the heart icon signifying "Wishlist" is a universally recognized symbol for saving or liking items. This icon's usage indicates its function, making it easy for users to save properties they're interested in. Similarly the icons for inbox, profile and maps are clearly identifiable. Also the presence of placeholders.

Constraints:

Constraints in Airbnb are particularly important when it comes to property bookings. For example, when **selecting dates for a stay**, the app enforces constraints by **graying out unavailable dates** or **restricting the selection to a specific check-in and check-out sequence**. This ensures users don't inadvertently select conflicting dates and helps in avoiding booking mistakes. Having the numpad only intrigued me again as the developers gave a thought into how only numbers would be entered and kept only the num pad visible. As a mobile application developer in the past this reminded me how they would've done it and how they went an extra mile.

Mapping:

Mapping in the Airbnb app is evident when users browse through property listings. The placement of photos, property details, and booking options follows a logical order. For example, the primary image of the property is usually at the top, followed by a brief description, pricing information, and user reviews. This consistent mapping makes it easy for users to find the information they need without confusion.

Feedback:

Airbnb provides feedback in real-time as users interact with the app. For instance, when scrolling through property photos, a subtle **bounce-back effect** is applied at the end of the photo gallery to indicate that you've reached the last image and a haptic feedback when you use the gestures to come out of a listing to a general page. When users complete a booking, they receive **immediate confirmation** with booking details, payment summaries, and an email confirmation. This feedback reassures users and keeps them informed about their actions. **Write more here**

Conceptual Models:

Having conceptual models was necessary and they seemed to have been completely missing. The application houses a lot of generic design patterns for users to get their way through the application, but the lack of conceptual models was instantly noticed. The application however had one sighting of a conceptual model where it showcased its host capabilities which I feel from a consumer stand point was misleading.
